Timer for NiCd and NiMH chargers

74LV4799

FEATURES

- Wide supply voltage range of 0.9 V to 6 V allows 1 to 4-cell applications
- 10 V allowed on special inputs
- Supports virtually all battery chargers, including switched-mode power supplies
- On-chip timer calculates the actual capacity of the battery by measuring the charger time, discharge time and self-discharge time
- Automatic switch-over to trickle charge after completion of the charge time
- Can be adjusted for use with different types of batteries:
 - Charge time: 4 to 16 hours
 - Discharge time: 15 minutes to 4.7 hours
 - Self-discharge time: 50 to 100 days
- Battery status indication included:
 - $\overline{\text{LED}}$ output for charging/full indication
 - $\overline{\text{MOLLI}}$ output for battery-low indication
- LED mode select allows two different methods of indication
- Automatic power-ON reset
- Low-power consumption
- Requires only a few peripheral components
- Very accurate on-chip oscillator
- Scan test facilities included
- I_{CC} category: non-standard.

APPLICATIONS

- Time-controlled NiCd and NiMH low-current chargers
- Domestic appliances such as rechargeable battery shavers, electric toothbrushes etc.
- Portable equipment such as notebook PCs, laptop PCs, camera flash units etc.
- Personal communications like cordless telephones, personal mobile radios, pagers, etc.

DESCRIPTION

The 74LV4799 is a low-voltage Si-gate CMOS control IC for battery management. It consists of:

- 17-stage divider
- 10-stage up/down counter
- Control logic
- Integrated precision oscillator (using external timing components)
- Automatic power-ON reset
- Scan test facilities
- Battery charging/full indication output ($\overline{\text{LED}}$)
- Battery-low indication output ($\overline{\text{MOLLI}}$)
- Open-drain-N outputs for driving the load transistor

Battery management with the 74LV4799 is based on the principle of time measurement. It measures the charge time, discharge time and self-discharge time by means of a very accurate on-chip oscillator, a divider and an up/down counter.

PIN CONFIGURATION

QUICK REFERENCE DATA

GND = 0V; $T_{\text{amb}} = 25^{\circ}\text{C}$

SYMBOL	PARAMETER	CONDITIONS	TYPICAL	TYPICAL	TYPICAL	UNIT
V_{CC}	DC supply voltage		0.9		6.0	V
I_{CC}	Operating supply current	$V_{\text{CC}} = 3.3\text{V}$; self-discharge mode; $R_{\text{S}} = 100\text{ k}\Omega$; $C_1 = 220\text{nF}$		36		μA
Δf	Oscillator frequency tolerance	$V_{\text{CC}} = 1\text{ to }6\text{ V}$			7	%

PIN DESCRIPTION

PIN NO.	SYMBOL	NAME AND FUNCTION
1	LED	LED driver output pin (active LOW)
2	EN	Enable output (active HIGH)
3	EN	Enable output (active LOW)
4	V _{in}	External power input
5	PWRS	Power sense input
6	MOLLI/SCO	More-or-less-low-indication output (active LOW)/scan test output
7	SEL	LED mode select input
8	GND	Ground (0 V)
9	DIS	Discharge input (active LOW)
10	R _C	External resistor pin 3-State oscillator output (charge)
11	R _D	External resistor pin 3-State output (discharge)
12	R _S	External resistor pin 3-State output (self-discharge)
13	I _{osc}	Oscillator input
14	SCAN	Scan test mode select input (active HIGH)
15	SCI	Scan test input
16	V _{CC}	Positive supply voltage

Power On Reset.

An automatic Power On Reset initiates the IC when the battery is discharged and power is connected to the circuit. The initial condition is the charge mode in which the counter is reset and counts from zero up to maximum. At start up, the battery therefore always receives a full charge cycle. When a partially charged battery is inserted, it may be over-charged during the first cycle. To guard against this, simply replace the resistor at the R_C pin with an NTC type which is in good thermal contact with the battery. If the temperature of the battery increases, the frequency of the oscillator also increases to quickly reach a counter full indication and switch-over to trickle charge. With a battery that is almost completely discharged, the POR input can also be activated during discharge or self-discharge. The counter will then be reset to zero. This is a correct action while returning to the initial condition.

Power-on sensing.

Because this IC supports virtually all battery chargers, the PWRS input has a broad input frequency spectrum (active HIGH to 100 kHz). A pull-down circuit at the PWRS input allows detection of the open state which corresponds to an inactive charger. A HIGH level on the PWRS input, or an AC signal up to 100 kHz, enables the charge mode.

Start-up with low battery voltage.

Good start-up, even with an un-charged battery, is assured by using the V_{IN} input. The voltage on the V_{IN} input biases the external bipolar transistors at the EN or EN outputs, even if the IC is not yet functioning. After the battery has received sufficient charge, the internal control logic takes over control of the EN and EN outputs.

Charge mode.

This mode is selected when PWRS is active (HIGH or pulsed) and the discharge input DIS is HIGH. The EN output is HIGH, and the EN output is LOW initiating continuous charge of the battery. The counter then counts from the zero state up to the maximum value. The clock frequency is determined by the external capacitor and resistor connected to the R_C output. The counter stops when it

reaches its maximum value and the EN and EN outputs switch over from the continuous charge to the trickle charge mode.

Trickle charge mode.

At the maximum counter value, it is assumed that the battery is fully charged. The counter stops and remains on this maximum value.

The EN and EN outputs switch over from the continues charge to the trickle charge mode. In the trickle charge mode, the average charge current is reduced to only compensate the self-discharge of the battery by using the dedicated duty cycle control. The control is dedicated because it adjusts the duty cycle in inverse proportion to the load current, resulting in a fixed charger current irrespective of the kind of charger (e.g. 4-hour or 16-hour charger). In the trickle charge mode, the oscillator circuitry alternately generates 4 periods of R_C -C1 time-constant, and 3 periods of the R_S -C1 time-constant (See Figure 1).

Discharge mode.

The discharge input (DIS) is used to detect the discharge of the battery. If DIS is LOW, the counter counts down. The clock frequency is determined by the external capacitor and resistor at the R_D output. If PWRS is inactive (LOW or open), the EN output is LOW, and the EN output is in the high impedance OFF-state (no charge of the battery). This is called the discharge mode. If PWRS is active, the circuit is in the charge/discharge mode.

Charge/Discharge mode.

If DIS is LOW and PWRS is active (HIGH or pulsed), the circuit is in the charge/discharge mode. The counter counts down. The clock frequency is determined by the external capacitor and resistor tied at the R_D output. The EN output is HIGH, and the EN output is LOW initiating continuous charge of the battery. The battery is therefore charged and discharged at the same instant, thereby maintaining a better load condition of the battery.

Timer for NiCd and NiMH chargers

74LV4799

Self-discharge mode.

If \overline{DIS} is HIGH and PWRS is inactive (LOW or open), the battery is being neither charged nor discharged. The circuit is in the self-discharge mode. This mode represents the battery leakage (self-discharge). The counter counts down. The clock frequency is determined by the external capacitor and resistor at the R_S output. When the counter reaches the zero state, it stops.

LED mode select.

The \overline{LED} output drives a battery status LED which indicates the charge/full status of the battery. For optimum flexibility, two modes of operation are built-in.

- Mode 1: If SEL is LOW, the \overline{LED} output is active LOW in the charge mode, and the LED blinks with a frequency of about 1 Hz during trickle charge.
- Mode 2: If SEL is HIGH or open, the LED output blinks with a frequency of about 0.25 Hz in the charge mode, and is active LOW during trickle charge. In the discharge or self-discharge mode, the LED output is open except when PWRS is active (HIGH or pulsed). Then, the battery is charging and discharging simultaneously. Although the discharge mode is dominant, the LED output is active when PWRS is also active.

NOTE: The blink frequency depends on the oscillator frequency. (See application information)

Low indication.

As part of the user interface, the \overline{MOLLI} output shows when the battery needs to be charged. \overline{MOLLI} stands for More Or Less Low Indication (active LOW). The function is as follows: In the discharge mode, (\overline{DIS} is active LOW), the counter counts down and, when it reaches the zero state, it stops. If \overline{DIS} is switched HIGH, the \overline{MOLLI} output gives an output signal of four periods of about one second, with a 50% duty cycle. This can be used to activate a buzzer. The \overline{MOLLI} output signal of four periods will be interrupted as soon as PWRS is activated.

Alarm indication.

If an almost completely discharged battery is connected to the charger, it may not be noticed by the user if the load switch is still

on. To prevent damaging the battery, an alarm signal on the \overline{LED} output will alert the user to switch off the load. The alarm signal is easily recognized, because the \overline{LED} output will blink at a higher frequency than normal (about 5 Hz instead of 1 Hz). This alarm indication is only active if the SEL input is HIGH or open. If the SEL input is LOW, no alarm indication is present, because in many applications simultaneous charging and discharging is quite acceptable. (See charge/discharge mode)

Scan test mode.

If the SCAN input (pin 14) is made active HIGH, the circuit is in the test mode. The tester clock is connected to the I_{OSC} pin (pin 13). In the scan mode, the on-chip oscillator is bypassed to allow rapid testing of the divider/counter. The scan test patterns are available on request. The scan test data is entered serially through the SCl input (pin 15). The scan out data is present on the \overline{MOLLI}/SCO output (pin 6), which then acts as a scan output.

Remaining energy indication.

The scan test facility can be used as a remaining energy indication because the value of the counter can be read out at the scan output (\overline{MOLLI}/SCO). This is done by briefly interrupting the normal mode of operation, putting the circuit in the scan mode, and reading out the counter value. The circuit then reverts to the normal mode. This only works correctly with the \overline{MOLLI}/SCO output and SCl input linked (round coupled loop) and with exactly 49 clock pulses applied to the I_{OSC} input.

The serial scan-out data is available on the \overline{MOLLI}/SCO output. The value of the counter can be decoded by reading the correct bits. Details are given later in the section "Application information".

Output drivers EN and \overline{EN} .

In one-cell battery (low-voltage) applications, the drive from the ENABLE output (\overline{EN}) is insufficient to provide the base current directly for the external bipolar PNP regulator transistor. The inverse signal has therefore been made available at the ENABLE output (EN) to drive an extra bipolar NPN transistor that can provide the base current for the bipolar PNP regulator transistor as shown in Figure 2.

FUNCTION TABLE 1

OPERATING MODES	INPUTS			OUTPUTS					DIVIDER/COUNTER	
	PWRS	V_{IN}	\overline{DIS}	EN	\overline{EN}	R_C	R_D	R_S	MODE	VALUE

P_{tot}	Power dissipation per package	for temperature range: –40 to +125 °C			mW
	Plastic DIL	above + 70 °C derate linearly with 12 mW/K		750	
	Plastic mini-pack (SO)	above + 70 °C derate linearly with 8 mW/K		500	
	Plastic shrink mini-pack (SSOP and TSSOP)	above + 60 °C derate linearly with 5.5 mW/K		400	

NOTES:

1. In applications where a motor is present, the input voltage may exceed the maximum V_I , level of 10 V at the \overline{DIS} input for a very short period when the motor is switched off.
2. Stresses beyond those listed may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those under "recommended operating conditions" is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.
3. The input and output voltage ratings may be exceeded if the input and output current ratings are observed.

		6.0		100					
f _{i(min)}	Minimum frequency at power sense input	1.0				50			Hz
		6.0				50			

NOTES:

- The oscillator frequency can be calculated by: $f = \frac{0.36}{R \times C1}$
- During blinking.
- An output signal of four periods will appear in case of discharged batteries and \overline{DIS} is switched HIGH.

APPLICATION INFORMATION**Oscillator.**

The frequency will be determined by the external components R_C, R_D, R_S, and C₁. The frequencies can be calculated by the following expressions: $f = \frac{0.36}{R_C \times C1}$; $f = \frac{0.36}{R_D \times C1}$; $f = \frac{0.36}{R_S \times C1}$.

R_C and C₁ determine the charge time.

R_D and C₁ determine the discharge time.

R_S and C₁ determine the self-charge time.

The charge, discharge and self-discharge times can be calculated as follows:

$$\text{Charge time} = \frac{2^{22}}{f_C}; \text{Discharge time} = \frac{2^{18}}{f_D}; \text{Self-discharge time} = \frac{2^{27}}{f_S}$$

In the trickle charge mode, the average charge current will be reduced by a factor: $\frac{1}{1 + \frac{3 \times R_S}{4 \times R_C}}$

Timer for NiCd and NiMH chargers

74LV4799

Charge discharge times

PARAMETER	TIME RANGE	CONDITIONS
Charge time	4 hours to 16 hours	Components ranges are within the values given in Section "External components range"
Discharge time	15 minutes to to 4.7 hours	
Self-discharge time	50 days to 100 days	

LED frequency

The frequency of the $\overline{\text{LED}}$ output (pin1) is determined by the oscillator frequency.

Three modes of operation, each with its own frequency, are possible.

Mode	SEL	LED frequency
Charge	H or open	$\frac{f_C}{256}$
Trickle charge	L	$\frac{1}{\frac{8}{f_C} + \frac{6}{f_S}}$
Alarm	H	$\frac{f_D}{32}$

MOLLI pulse duration

The MOLLI output gives an output signal of four periods with a 50% duty cycle. The duration of one period is determined by: $16/f_S$

Timing accuracy.

The timing accuracy depends on the accuracy of the on-chip oscillator and on the external R and C components. The inaccuracy of the on-chip oscillator is specified as maximum $\pm 7\%$. In most cases the actual inaccuracy will be significantly lower. This depends on the supply voltage as well as the value of the external components.

Influence of Resistor value.

Low resistor values cause some spread because the RC combination is biased by a 3-State push-pull output. The spread of

the R_{ON} of the push-pull stage will contribute to the frequency spread. When high-value resistors are used, any possible output leakage of the not-selected 3-State outputs will cause a frequency deviation. For these reasons, the resistor values must be within the specified ranges.

Influence of supply voltage

The trip levels of the oscillator are fixed at 20% and 80% of V_{CC} . At higher supply voltages the spread of the trip levels decreases in greater proportion because the offset voltage remains constant, and the propagation delay decreases. Furthermore, the R_{ON} values of the push-pull driving stage decrease at higher voltages.

SPREAD-CAUSING FACTORS

SYMBOL	PARAMETER	V_{CC} (V)	T_{amb} (°C)			UNIT
			MIN	TYP	MAX	
V_{off}	Offset voltage	1.0		7		mV
		6.0		7		mV
t_p	Propagation delay	1.0		22		μs
		6.0		5.5		μs
R_{ON}	P-channel resistance R_C , R_D outputs	1.0		170		Ω
		6.0		25		Ω
R_{ON}	N-channel resistance R_C , R_D outputs	1.0		250		Ω
		6.0		35		Ω
R_{ON}	P-channel resistance R_S output	1.0		1300		Ω
		6.0		180		Ω
R_{ON}	N-channel resistance R_S output	1.0		1300		Ω
		6.0		180		Ω

Error free operation, even under extreme conditions.

Several measures are taken in the circuit design to ensure error-free operation, even with very low supply voltages. Moreover, the circuit has been made very insensitive to the effects of external fields. The measures taken during the design are:

- Use of synchronous logic
- Bistable POR instead of monostable POR
- Data retention assured below a supply voltage of 0.9 V.
- Debounce circuitry on \overline{DIS} input (maximum expected debounce time = 10 ms)
- Schmitt trigger on PWRS (power sense) input and on \overline{DIS} input
- Special oscillator security to prevent any malfunction.

Synchronous logic and bistable POR.

Use of synchronous logic results in much lower sensitivity to spikes on input pins. The POR is adapted to fit well into a synchronous environment. An increasing supply voltage sets the POR. The POR output signal is routed to the control logic and divider/counter. It is synchronized with the on-chip clock. After all flip-flops are reset, a reset acknowledge signal is generated which resets the POR. This method ensures that the POR signal is acknowledged in all cases, even at very low voltages.

Data retention.

The circuit may be used in an application where an electric motor is present. When the motor is switched on, it will disturb the supply voltage for a short period. The POR level is set at such a level that, even with very low supply voltages, the POR will not respond during motor switch on. The flip-flops will retain their data during the supply voltage disturbance because of the inherent data retention of any CMOS gate. However, when the battery is almost completely discharged and the motor switch is activated, the dip on the supply voltage line can be too large. The retention of the POR is therefore made deliberately worse than that of the internal flip-flops. The POR will therefore respond long before the flip-flops will lose their data. This results in a proper start condition for a new charge cycle.

Debounce circuitry on \overline{DIS} input.

A discharge cycle is activated by a switch. To protect the circuit from any bounce of the switch contacts, de-bounce circuitry is provided

at the \overline{DIS} input. The circuitry allows a switch de-bounce time of max. 10 ms.

Schmitt trigger on PWRS (power sense) input.

The PWRS input can be corrupted by high transients due to disturbances on the mains supply. To suppress any false triggering, the PWRS input is provided with a Schmitt-trigger. However, for some applications, it is advisable to connect a low-value capacitor (150 pF min.) between the PWRS input and GND.

Special oscillator security to prevent any malfunction.

The excellent performance of the oscillator is achieved by using linear op-amp techniques. The oscillator consists of an internal reference, two comparators and a latch. Care was taken to design a very reliable oscillator even with a supply voltage below 0.9 V. If one of the comparators ceases to operate with a supply voltage below 0.9 V, the latch will not be corrupted. Priority was given to stop the oscillator rather than allow uncontrolled oscillation.

All these measures result in reliable 1-cell to 4-cell battery charge management.

Remaining energy indication:

The scan test facility can be used as a remaining energy indication because the value of the counter can be read-out at the scan output (\overline{MOLLI}/SCO). This is achieved by briefly interrupting the normal mode of operation, putting the circuit in the scan mode (pin 14 = HIGH), and reading-out of the counter value. The circuit is then returned to the normal mode (pin 14 = LOW or open).

Read-out procedure: The contents of the counter flip-flops can be read-out in the scan mode. To ensure that there is no disturbance of the circuit function, it is essential to either create a round coupled loop by linking the \overline{MOLLI}/SCO output (pin 6) directly to the SCI input pin 15), or to shift-in the serial data of the scan line at the SCI input after completion of the read out cycle. 49 clock pulses are needed on the \overline{losc} input (pin 13) to shift-out the contents of the whole scan line. The most-significant bit of the counter will appear at the \overline{MOLLI}/SCO output after the last clock pulse. The least-significant bit after the penultimate clock pulse, etc. Selecting the last three or four bits will yield sufficiently high accuracy to obtain the counter value which represents the remaining energy of the battery.

Data sheet status

Data sheet status	Product status	Definition [1]
Objective specification	Development	This data sheet contains the design target or goal specifications for product development. Specification may change in any manner without notice.
Preliminary specification	Qualification	This data sheet contains preliminary data, and supplementary data will be published at a later date. Philips Semiconductors reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.
Product specification	Production	This data sheet contains final specifications. Philips Semiconductors reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.

[1] Please consult the most recently issued datasheet before initiating or completing a design.

Definitions

Short-form specification — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

Limiting values definition — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Disclaimers

Life support — These products are not designed for use in life support appliances, devices or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

Right to make changes — Philips Semiconductors reserves the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.

Let's make things better.

ООО «НИОКРсистемс» - это оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов. Реализуемая нашей компанией продукция насчитывает более полумиллиона наименований.

Благодаря этому наша компания предлагает к поставке практически не ограниченный ассортимент компонентов как оптовыми, мелкооптовыми партиями, так и в розницу.

Благодаря развитой сети поставщиков, помогаем в поиске и приобретении экзотичных или снятых с производства компонентов.

Наша компания это:

- Гарантия качества поставляемой продукции
- Широкий ассортимент
- Минимальные сроки поставок
- Техническая поддержка
- Подбор комплектации
- Индивидуальный подход
- Гибкое ценообразование
- Работаем по 275 ФЗ
