ANALOG DEVICES

Multichannel,
24-Bit, 192 kHz, Σ-Δ DAC

AD1833

FEATURES
5 V Stereo Audio System with 3.3 V Tolerant Digital Interface
Supports 96 kHz Sample Rates on Six Channels and 192 kHz on 2 Channels
Supports 16-/20-/24-Bit Word Lengths
Multibit Sigma-Delta Modulators with "Perfect Differential Linearity Restoration" for Reduced Idle Tones and Noise Floor
Data Directed Scrambling DACs—Least Sensitive to Jitter
Differential Output for Optimum Performance
DACs Signal-to-Noise and Dynamic Range: 110 dB
–94 dB THD + N—6-Channel Mode
–95 dB THD + N—2-Channel Mode
On-Chip Volume Control Per Channel with 1024-Step Linear Scale
Software Controllable Clickless Mute
Digital De-Emphasis Processing
Supports 256 × f_S, 512× f_S, and 768× f_S Master Clock Modes
Power-Down Mode Plus Soft Power-Down Mode
Flexible Serial Data Port with Right-Justified, Left-Justified, I²S-Compatible and DSP Serial Port Modes
**Supports Packed Data Mode (TDM) for DACs**
48-Lead LQFP Plastic Package

APPLICATIONS
DVD Video and Audio Players
Home Theatre Systems
Automotive Audio Systems
Set-Top Boxes
Digital Audio Effects Processors

GENERAL DESCRIPTION
The AD1833 is a complete, high-performance, single-chip, multichannel, digital audio playback system. It features six audio playback channels each comprising a high-performance digital interpolation filter, a multibit sigma-delta modulator featuring Analog Devices patented technology and a continuous-time voltage-out analog DAC section. Other features include an on-chip clickless attenuator and mute capability, per channel, programmed through an SPI-compatible serial control port.

FUNCTIONAL BLOCK DIAGRAM
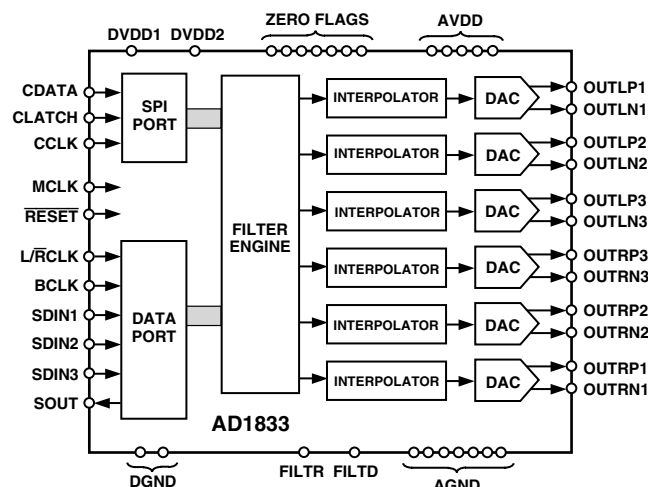

The AD1833 is fully compatible with all known DVD formats, catering for up to 24-bit word lengths at sample rates of 48 kHz and 96 kHz on all six channels while supporting a 192 kHz sample rate on two channels. It also provides the "Redbook" standard 50 μs/15 μs digital de-emphasis filters at sample rates of 32 kHz, 44.1 kHz, and 48 kHz.

The AD1833 has a very flexible serial data input port that allows for glueless interconnection to a variety of ADCs, DSP chips, AES/EBU receivers, and sample rate converters. The AD1833 can be configured in left-justified, I²S, right-justified, or DSP serial port compatible modes. The AD1833 accepts serial audio data in MSB first, two's complement format. While the AD1833 can be operated from a single 5 V power supply, it also features a separate supply pin for its digital interface which allows the device to be interfaced to devices using 3.3 V power supplies.

It is fabricated on a single monolithic integrated circuit and is housed in a 48-lead LQFP package for operation over the temperature range –40°C to +85°C.

AD1833

FUNCTIONAL DESCRIPTION

Device Architecture

The AD1833 is a 6-channel audio DAC featuring multibit Sigma-Delta (Σ-Δ) technology. The AD1833 features three stereo converters (giving six channels) where each stereo channel is controlled by a common bit-clock (BCLK) and synchronization signal (L/$\overline{R}$CLK).

Interpolator

The interpolator consists of up to three stages of sample rate doubling and half-band filtering followed by a 16 sample zero order hold. The sample rate doubling is achieved by zero stuffing the input samples, and a digital half band filter is then used to remove any images above the band of interest and to bring the zero samples to their correct values.

By selecting different input sample rates, one, two, or all three stages of doubling may be switched in. This allows for three different sample rate inputs. All three doubling stages are used with the 48 kHz input sample rate, with the 96 kHz input sample rate only two doubling stages are used, and with the 192 kHz input sample rate only one doubling stage is used. In each case the input sample frequency is increased to 384 kHz. The Zero-Order Hold (ZOH) holds the interpolator samples for upsampling by the modulator. This is done at a rate 16 times the interpolator output sample rate.

Modulator

The modulator is a 6-bit, second-order implementation and uses data scrambling techniques to achieve perfect linearity.

The modulator samples the output of the interpolator stage(s) at a rate of 6.144 MHz.

OPERATING FEATURES

SPI Register Definitions

The SPI port allows flexible control of the devices' programmable functions. It is organized around nine registers; six individual channel VOLUME registers and three CONTROL registers. Each WRITE operation to the AD1833 SPI control port requires 16 bits of serial data in MSB-first format. The four most significant bits are used to select one of nine registers (seven register addresses are reserved), and the bottom 10 bits are then written to that register. This allows a write to one of the nine registers in a single 16-bit transaction. The SPI CCLK signal is used to clock in the data. The incoming data should change on the falling edge of this signal and remain valid during the rising edge. At the end of the 16 CCLK periods, the CLATCH signal should rise to latch the data internally into the AD1833. See Figure 2.

The serial interface format used on the Control Port utilizes a 16-bit serial word as shown in Table I. The 16-bit word is divided into several fields: Bits 15–12 define the register address, Bits 11 and 10 are reserved and must be programmed to 0, and Bits 9–0 are the data field (which has specific definitions, depending on the register selected).

*Must be programmed to zero.

DAC CONTROL REGISTER I
De-Emphasis
The AD1833 has a built-in de-emphasis filter that can be used to decode CDs that have been encoded with the standard "Redbook" 50 µs/15 µs emphasis response curve. Three curves are available; one each for 32 kHz, 44.1 kHz, and 48 kHz sampling rates. The filters may be selected by writing to Control Bits 9 and 8 in DAC Control Register I, see Table III.

Table III. De-Emphasis Settings

Bit 9	Bit 8	De-Emphasis
0	0	Disabled
0	1	44.1 kHz
1	0	32 kHz
1	1	48 kHz

Data Serial Interface Mode
The AD1833's serial data interface is designed to accept data in a wide range of popular formats including I^{2}S, right justified (RJ), left justified (LJ) and flexible DSP modes. The L/$\overline{R}$CLK pin acts as the word clock (or Frame Sync) to indicate sample interval boundaries. The BCLK defines the serial data rate while the data is input on the SDIN1-3 pins. The serial mode settings may be selected by writing to Control Bits 7 through 5 in DAC Control Register I, see Table IV.

Table IV. Data Serial Interface Mode Settings

Bit 7	Bit 6	Bit 5	Serial Mode
0	0	0	I^{2}S
0	0	1	Right Justify
0	1	0	DSP
0	1	1	Left Justify
1	0	0	Packed Mode 1 (256)
1	0	1	Packed Mode 2 (128)
1	1	0	AUX Mode
1	1	1	Reserved

DAC Word Width
The AD1833 will accept input data in three separate word-lengths—16, 20, and 24 bits. The word-length may be selected by writing to Control Bits 4 and 3 in DAC Control Register I, see Table V.

Table V. Word Length Settings

Bit 4	Bit 3	Word Length
0	0	24 Bits
0	1	20 Bits
1	0	16 Bits
1	1	Reserved

Power-Down Control
The AD1833 can be powered down by writing to Control Bit 2 in DAC Control Register I, see Table VI. The power-down/reset bit is not latched when the CLATCH is brought high to latch the entire word, but only after the following low-to-high CLATCH transition. Therefore, to put the part in power-down, or to bring it back up from power-down, the command should be written twice.

Table VI. Power-Down Control

Bit 2	Power-Down Setting
0	Normal Operation
1	Power-Down Mode

Interpolator Mode
The AD1833's DAC interpolators can be operated in one of three modes—8×, 4×, or 2× corresponding with 48 kHz, 96 kHz, and 192 kHz modes respectively. The Interpolator Mode may be selected by writing to Control Bits 1 and 0 in DAC Control Register I, see Table VII.

Table VII. Interpolator Mode Settings

Bit 1	Bit 0	Interpolator Mode
0	0	8× (48 kHz)
0	1	2× (192 kHz)
1	0	4× (96 kHz)
1	1	Reserved

AD1833

*Must be programmed to zero.

DAC CONTROL REGISTER II

DAC Control Register II contains individual channel mute controls for each of the 6 DACs. Default operation (bit = 0) is muting off. Bits 9 through 6 of Control Register II are reserved and should be programmed to zero, see Table VIII.

Table IX. Muting Control

Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Muting
X	X	X	X	X	1	Mute Channel 1
X	X	X	X	1	X	Mute Channel 2
X	X	X	1	X	X	Mute Channel 3
X	X	1	X	X	X	Mute Channel 4
X	1	X	X	X	X	Mute Channel 5
1	X	X	X	X	X	Mute Channel 6

DAC CONTROL REGISTER III
Stereo Replicate

The AD1833 allows the stereo information on Channel 1 (SDIN1—Left 1 and Right 1) to be copied to Channels 2 and 3 (Left/Right 2 and Left/Right 3). These signals can be used in an external summing amplifier to increase potential signal SNR. Stereo Replicate mode can be enabled by writing to Control Bit 5, see Table XI. Note that replication is not reflected in the zero flag status.

Table XI. Stereo Replicate

Bit 5	Stereo Mode
0	Normal
1	Channel 1 Data Replicated on Channels 2 and 3

Table X. DAC Control III

Address	Reserved*		Reserved*	Function			
				Stereo Replicate (192 kHz)	MCLK Select	Zero Detect	Reserved
15–12	**11**	**10**	**9–6**	**5**	**4–3**	**2**	**1–0**
1000	0	0	0	0 = Normal 1 = Replicate	00 = 256 × f_S (MCLK × 2) 01 = 512 × f_S (MCLK Straight Through) 10 = 768 × f_S (MCLK × 2/3)	0 = Active High 1 = Active Low	

*Must be programmed to zero.

MCLK Select

The AD1833 allows the matching of available external MCLK frequencies to the required sample rate. The oversampling rate can be selected from $256 \times f_S$, $512 \times f_S$ or $768 \times f_S$ by writing to Bit 4 and Bit 3. Internally the AD1833 requires an MCLK of $512 \times f_S$; therefore, in the case of $256 \times f_S$ mode, a clock doubler is used, whereas in $768 \times f_S$ mode, a divide-by-3 block (/3) is first implemented, followed by a clock doubler. See Table XII.

Table XII. MCLK Settings

Bit 4	Bit 3	Oversample Ratio
0	0	$256 \times f_S$ (MCLK $\times$ 2 Internally)
0	1	$512 \times f_S$
1	0	$768 \times f_S$ (MCLK $\times$ 2/3 Internally)
1	1	Reserved

Channel Zero Status

The AD1833 provides individual logic output status indicators when zero data is sent to a channel for 1024 or more consecutive sample periods. There is also a global zero flag that indicates all channels contain zero data. The polarity of the active zero signal is programmable by writing to Control Bit 2, see Table XIII. The six individual channel flags are best used as three stereo zero flags by combining pairs of them through suitable logic gates. Then, when both the left and right input are zero for 1024 clock cycles, i.e., a stereo zero input for 1024 sample periods, the combined result of the two individual flags will go active indicating a stereo zero.

Table XIII. Zero Detect

Bit 2	Channel Zero Status
0	Active High
1	Active Low

DAC Volume Control Registers

The AD1833 has six volume control registers, one each for the six DAC channels. Volume control is exercised by writing to the relevant register associated with each DAC. This setting is used to attenuate the DAC output. Full-scale setting (all 1s) is equivalent to zero attenuation. See Table XV.

Table XIV. MCLK vs. Sample Rate Selection

Sampling Rate f_S (kHz)	Interpolator Mode	MCLK (MHz)		
		256 f_S	512 f_S	768 f_S

*Must be programmed to zero.

AD1833

I²S Timing

I²S timing uses an L/$\overline{\text{R}}$CLK to define when the data being transmitted is for the left channel and when it is for the right channel. The L/$\overline{\text{R}}$CLK is low for the left channel and high for the right channel. A bit clock running at $64 \times f_S$ is used to clock in the

data. There is a delay of one bit clock from the time the L/$\overline{\text{R}}$CLK signal changes state to the first bit of data on the SDINx lines. The data is written MSB first and is valid on the rising edge of bit clock.
Figure 4. I²S Timing Diagram

Left Justified Timing

Left Justified (LJ) timing uses an L/$\overline{\text{R}}$CLK to define when the data being transmitted is for the left channel and when it is for the right channel. The L/$\overline{\text{R}}$CLK is high for the left channel and

low for the right channel. A bit clock running at $64 \times f_S$ is used to clock in the data. The first bit of data appears on the SDINx lines at the same time the L/$\overline{\text{R}}$CLK toggles. The data is written MSB first and is valid on the rising edge of bit clock.
Figure 5. Left-Justified Timing Diagram

Right Justified Timing

Right Justified (RJ) timing uses an L/$\overline{\text{R}}$CLK to define when the data being transmitted is for the left channel and when it is for the right channel. The L/$\overline{\text{R}}$CLK is high for the left channel and low for the right channel. A bit clock running at $64 \times f_S$ is used

to clock in the data. The first bit of data appears on the SDINx 8-bit clock periods (for 24-bit data) after L/$\overline{\text{R}}$CLK toggles. In RJ mode the LSB of data is always clocked by the last bit clock before L/$\overline{\text{R}}$CLK transitions. The data is written MSB first and is valid on the rising edge of bit clock.

Figure 6. Right-Justified Timing Diagram

AUX-Mode Timing—Interfacing to a SHARC®

In AUX mode, the AD1833 is the master and generates a frame sync signal (FSTDM) on its L/$\overline{R}$CLK pin, and a bit clock (BCLKTDM) on its BCLK pin, both of which are used to control the data transmission from the SHARC. The bit clock runs at a frequency of $256 \times f_S$. In this mode all data is written on the rising edge of the bit clock and read on the falling edge of the bit clock. The AD1833 starts the frame by raising a frame sync on the rising edge of bit clock. The SHARC recognizes this on the following falling edge of bit clock, and is ready to start outputting data on the next rising edge of bit clock. Each channel is given a 32-bit clock slot, the data is left justified and uses 16, 20, or 24 of the 32 bits. An enlarged diagram (see Figure 6) is provided detailing this. The data is sent from the SHARC to the AD1833 on the SDIN1 pin and is provided in the following order, MSB first—Internal DACL0, Internal DACL1, Internal DACL2, AUX DACL0, Internal DACR0, Internal DACR1, Internal DACR2 and AUX DACR0. The data is written on the rising edge of bit clock and read by the AD1833 on the falling edge of bit clock. The left and right

data destined for the auxiliary DAC is sent to it in standard I^{2}S format in the next frame using the SDIN2, SDIN3, and SOUT pins as the L/$\overline{R}$CLK, BCLK, and SDIN pins respectively for communicating with the auxiliary DAC.

DSP Mode Timing

DSP Mode Timing uses the rising edge of the frame sync signal on the L/$\overline{R}$CLK pin to denote the start of the transmission of a data word. Note that for both left and right channels a rising edge is used; therefore in this mode there is no way to determine which data is intended for the left channel and which is intended for the right. The DSP writes data on the rising edge of BCLK and the AD1833 reads it on the falling edge. The DSP raises the frame sync signal on the rising edge of BCLK and then proceeds to transmit data, MSB first, on the next rising edge of BCLK. The data length can be 16, 20, or 24 bits. The frame sync signal can be brought low any time at or after the MSB is transmitted, but must be brought low at least one BCLK period before the start of the next channel transmission.

AD1833

Packed Mode 128

In Packed Mode 128, all six data channels are "packed" into one sample interval on one data pin. The BCLK runs at $128 \times f_S$; therefore there are 128 BCLK periods in each sample interval. Each sample interval is broken into eight time slots, six slots of 20 BCLKs and two of four BCLKs. The data length is restricted in this mode to a maximum of 20 bits. The three left channels are written first, MSB first, and the data is written on the falling edge of BCLK. After the three left channels are written, there is a space of four BCLKs and then the three right channels are written. The L/$\overline{\text{R}}$CLK defines the left and right data transmission; it is high for the three left channels and low for the three right channels.

Packed Mode 256

In Packed Mode 256 all six data channels are "packed" into one sample interval on one data pin. The BCLK runs at $256 \times f_S$; therefore there are 256 BCLK periods in each sample interval. Each sample interval is broken into eight time slots of 32 BCLKs each. The data length can be 16, 20, or 24 bits. The three left channels are written first, MSB first, and the data is written on the falling edge of BCLK with a one BCLK period delay from the start of the slot. After the three left channels are written, there is a space of 32 BCLKs and then the three right channels are written. The L/$\overline{\text{R}}$CLK defines the left and right data transmission; it is low for the three left channels and high for the three right channels.

48-Lead Thin Plastic Quad Flatpack
(ST-48)

ООО «НИОКРсистемс» - это оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов. Реализуемая нашей компанией продукция насчитывает более полумиллиона наименований.

Благодаря этому наша компания предлагает к поставке практически не ограниченный ассортимент компонентов как оптовыми, мелкооптовыми партиями, так и в розницу.

Благодаря развитой сети поставщиков, помогаем в поиске и приобретении экзотичных или снятых с производства компонентов.

Наша компания это:

• Гарантия качества поставляемой продукции

• Широкий ассортимент

• Минимальные сроки поставок

• Техническая поддержка

• Подбор комплектации

• Индивидуальный подход

• Гибкое ценообразование

• Работаем по 275 ФЗ
